Testing for Programmers, Brian Marick, Available at:
<http://www.testing.com/writings.html>

Just for Fun Reading a Webpage

```
import urllib2

webPage = urllib2.urlopen('http://www.elis.sdsu.edu')

print webPage.info()      #print http headers

for line in webPage:      #print out page contents
    print line,
```

Sending Mail

```
import smtplib

mailServer = smtplib.SMTP('cs.sdsu.edu')
sender = 'whitney@cs.sdsu.edu'
receiver = 'whitney@rohan.sdsu.edu'
message = """To: whitney@rohan.sdsu.edu
From: whitney@cs.sdsu.edu"""

This is a sample email.
```

```
"""
mailServer.sendmail(sender, receiver, message)
mailServer.quit()
```

A Web Spider

```
import re, urllib2

hrefsIn(aString):
    return aString.split( '</a>')

def linkIn(aHref):
    pattern = re.compile('href="([^\"]+)"',re.IGNORECASE)
    result = pattern.search(aHref)
    if result:
        return result.groups()[0]
    else:
        return ""

def linksIn(aString):
    linksAndEmpty = map(linkIn, hrefsIn(aString))
    return filter(lambda x: x != "", linksAndEmpty)

def spider(aUrl):
    webPage = urllib2.urlopen(aUrl)
    links = []
    for line in webPage:
        links = links + linksIn(line)
    return links

print spider(http://www.elis.sdsu.edu/)
```

Lambda Environments

```
x = 5
```

```
test = lambda y: x + y
print test(1)          #prints 6
```

```
x = 20
print test(1)          #prints 21
```

```
def local(function):
    x = 10
    print function(1)
```

```
local(test)          #prints 21
```

```
def localEnvironment():
    z = 10
    return lambda y: y + z
```

```
z = 2
function = localEnvironment();
print function(1)      #prints 11
```

Exceptions Catching an Exception

General forms

```
try:  
    <block>  
except <name>:  
    <except block>  
except <name> , <data>:  
    <except block2>  
else:  
    <else block>
```

```
try:  
    <block>  
finally:  
    <finally block>
```

```
def myBad(list, index):  
    print list[index]
```

```
try:  
    myBad([0, 1], 3)  
except IndexError:  
    print 'BadIndex'
```

[Built-in Exceptions](#)

Defining an Exception

```
class SampleError(Exception):
    pass

try:
    raise SampleError
except SampleError:
    print 'I got it'
else:
    print 'No Error'
```

Modules Simple Example

In a file called eli.py place:

```
def whitney():
    print 'whitney'
```

This is now a module which can be used by python code

Using the Module

```
import eli
eli.whitney()
```

How Python finds Modules

Python interpreter searches in order:

- Current directory
- Directories listed in environment variable PYTHONPATH
- Installation-dependent path for standard modules

So create a directory for your modules and set your PYTHONPATH to include that directory

Unix Example

Setting PYTHONPATH

```
setenv PYTHONPATH /Users/whitney/Courses/683/Fall05/pythonCode/  
modules
```

Now place the file eli.py in the directory

```
/Users/whitney/Courses/683/Fall05/pythonCode/modules
```

and from any location on the machine run:

```
import eli  
whitney()
```

sys.path and PYTHONPATH

sys.path contains the PYTONPATH

sys.path can be accessed and changed at runtime

```
import sys  
print sys.path  
  
sys.path.append('/Users/whitney/Courses/683/Fall  
05/pythonCode/modules')  
print sys.path  
  
import eli  
eli.whitney()
```

Import statement

Simple import

Need to use full name of module elements

```
import eli  
eli.whitney()
```

Import with names

Can use short name of imported element

```
from eli import whitney  
whitney()
```

Import all names

* imports all names from the module except those starting with _

```
from eli import *  
whitney()
```

Modules and Executable code

ely.py

```
x = 0
y = [1, 2]
print 'eli module run'

def whitney():
    print 'whitney'

def printValues()
    print x , y
```

When loaded for the first time code in the module is run

Example

```
import eli
eli.whitney()
from eli import y
print y
```

Output

```
eli module run
whitney
[1, 2]
```

Reloading a module

if you need to reload a module use `reload()`

Example

```
import eli  
eli.y[0] = 'cat'  
eli.printValues()  
  
reload(eli)  
eli.printValues()
```

Output

```
eli module run  
0 ['cat', 2]  
eli module run  
0 [1, 2]
```

Explain this One! ely.py

```
x = 0  
y = [1, 2]  
print 'eli module run'
```

```
def printValues():  
    print x , y
```

Program

```
from eli import x, y, printValues  
  
printValues()  
y[0] = 'cat'  
x = 'dog'  
printValues()
```

Output

```
0 [1, 2]  
0 ['cat', 2]
```

dir()

List all names defined in a module

```
import sys, eli  
  
print dir(eli)  
print dir(sys)
```

Output

```
['__builtins__', '__doc__', '__file__', '__name__', 'printValues', 'x', 'y']  
  
['__displayhook__', '__doc__', '__excepthook__', '__name__', '__stderr__',  
'__stdin__', '__stdout__', '_getframe', 'api_version', 'argv',  
'builtin_module_names', 'byteorder', 'call_tracing', 'callstats', 'copyright',  
some lines removed here  
'setdlopenflags', 'setprofile', 'setrecursionlimit', 'settrace', 'stderr',  
'stdin', 'stdout', 'version', 'version_info', 'warnoptions']
```

Packages

Hierarchal modules

`foo.bar.whitney()`

Example

In a directory in PYTHONPATH create a subdirectory -
foo

In foo place an `__init__.py` file (it can be empty)

Any `.py` file in foo is now an accessible module

The file `test.py` is now `foo.test`

Can nest directories

Program and imported Module

`__name__`

- Module attribute
- Set to '`__main__`' if file is run a program
- Set to module name if file is imported as a module

Example

```
def hello():
    print 'Hello'

if __name__ == '__main__':
    hello()
```

As Program

```
AI 60->python nameExample.py
Hello
```

As Module

```
import nameExample
nameExample.hello()
```

Output

```
Hello
```

XUnit tests

Example

Queue code to test

```
class Queue:  
    def __init__(self):  
        self._elements = []  
  
    def size(self):  
        return len(self._elements)  
  
    def enqueue(self, a):  
        self._elements.append(a)  
  
    def dequeue(self):  
        first = self._elements[0]  
        self._elements = self._elements[1:]  
        return first
```

Test Code

```
import unittest

class TestQueue(unittest.TestCase):

    def testEnqueue(self):
        queue = Queue()
        self.assertEqual(queue.size(), 0)
        queue.enqueue(1)
        self.assertEqual(queue.size(), 1)

    def testDequeue(self):
        queue = Queue()
        queue.enqueue(1)
        queue.enqueue(2)
        queue.enqueue(3)
        self.assertEqual(queue.size(), 3)
        self.assertEqual(queue.dequeue(), 1)
        self.assertEqual(queue.size(), 2)
        self.assertEqual(queue.dequeue(), 2)
        self.assertEqual(queue.size(), 1)
        self.assertEqual(queue.dequeue(), 3)
        self.assertEqual(queue.size(), 0)

    if __name__ == '__main__':
        unittest.main()
```

main runs all methods starting with 'test'

Result of Running the tests

..

Ran 2 tests in 0.000s

OK

What happens if tests fail?

```
import unittest

class TestQueue(unittest.TestCase):

    def testEnqueue(self):
        queue = Queue()
        self.assertEqual(queue.size(), 42)
        queue.enqueue(1)
        self.assertEqual(queue.size(), 1)

    if __name__ == '__main__':
        unittest.main()
```

Output

```
F
=====
FAIL: testEnqueue (__main__.TestQueue)
-----
-----
Ran 1 test in 0.004s
FAILED (failures=1)
```

Plus debugger opens on error

setUp & tearDown

setUp() is run before each test method

tearDown() is run after each test method

```
import unittest

class TestQueue(unittest.TestCase):
    def setUp(self):
        self.queue = Queue()

    def testEnqueue(self):
        self.assertEqual(self.queue.size(), 0)
        self.queue.enqueue(1)
        self.assertEqual(self.queue.size(), 1)

    def testDequeue(self):
        self.queue.enqueue(1)
        self.queue.enqueue(2)
        self.assertEqual(self.queue.size(), 2)
        self.assertEqual(self.queue.dequeue(), 1)
        self.assertEqual(self.queue.size(), 1)
        self.assertEqual(self.queue.dequeue(), 2)
        self.assertEqual(self.queue.size(), 0)

    if __name__ == '__main__':
        unittest.main()
```

Some Useful TestCase methods

- assert_(expression)
- failUnless(expression)

- assertEquals(first, second[, msg])
- failUnlessEqual(first, second[, msg])

- assertNotEqual(first, second[, msg])
- failIfEqual(first, second[, msg])

- assertAlmostEqual(first, second[, places[, msg]])
- failUnlessAlmostEqual(first, second[, places[, msg]])

- assertNotAlmostEqual(first, second[, places[, msg]])
- failIfAlmostEqual(first, second[, places[, msg]])

- assertRaises(exception, callable, ...)
- failUnlessRaises(exception, callable, ...)

See on-line [docs](#) for details

Testing Exceptions

```
import unittest

class TestQueue(unittest.TestCase):
    def setUp(self):
        self.queue = Queue()

    def testEnqueue(self):
        self.assertEqual(self.queue.size(), 0)
        self.queue.enqueue(1)
        self.assertEqual(self.queue.size(), 1)

    def testEmptyDequeue(self):
        self.assertRaises(IndexError, self.queue.dequeue)

if __name__ == '__main__':
    unittest.main()
```

Why Unit Testing

If it is not tested it does not work

The more time between coding and testing

- More effort is needed to write tests
- More effort is needed to find bugs
- Fewer bugs are found
- Time is wasted working with buggy code
- Development time increases
- Quality decreases

Without unit tests

- Code integration is a nightmare
- Changing code is a nightmare

Why Automated Tests?

What is wrong with:

- Using print statements
- Writing driver program in main
- Writing small sample programs to run code
- Running program and testing it by using it

Repeatability & Scalability

Need testing methods that:

- Work with N programmers working for K months (years)
- Help when modify code 6 months after it was written
- Check impact of code changes in rest of system

Practices that work in a school project may not be usable in industry

Standard industry practices may seem overkill in a school project

Work on building good habits and skills

We have a QA Team, so why should I write tests?

How long does it take QA to test your code?

How much time does your team spend working around bugs before QA tests?

How easy is it to find & correct the errors after QA finds them?

Most programmers have an informal testing process

With a little more work you can develop a useful test suite

When to Write Unit Tests

First write the tests

Then write the code to be tested

Writing tests first saves time

- Makes you clear of the interface & functionality of the code
- Removes temptation to skip tests

What to Test

Everything that could possibly break

Test values

- Inside valid range
- Outside valid range
- On the boundary between valid/invalid

GUIs are very hard to test

- Keep GUI layer very thin
- Unit test program behind the GUI, not the GUI

Common Things Handled Incorrectly

Adapted with permission from "A Short Catalog of Test Ideas" by Brian Marick,
<http://www.testing.com/writings.html>

Strings

Test using empty String

Collections

Test using:

- Empty Collection
- Collection with one element
- Collection with duplicate elements
- Collections with maximum possible size

Numbers

Test using:

- Zero
- The smallest number
- Just below the smallest number
- The largest number
- Just above the largest number

JUnit

Free frameworks for Unit testing

JUnit written by Kent Beck & Erich Gamma

Available at: <http://www.junit.org/>

Ports are available in at least

.NET	Ada	AppleScript	C
C#	C++	Curl	Delphi
Eiffel	Eiffel	Flash	Forte 4GL
Gemstone/S	Haskell	HTML	Jade
LISP	Objective-C	Oracle	Palm
Perl	Php	PowerBuilder	Python
Ruby	Scheme	Smalltalk	Visual Basic
XML	XSLT
